BAYANI BITE Campus Food Hub Rescue Long Test

90 minutes | 100 points | Chapters 1 to 6 | Individual | Open tool and open AI

Your mission

Build an interactive prototype dashboard that helps BAYANI BITE's board understand growing crowds and operating losses, and choose a four-week pilot for Weeks 13 to 16. Apply Chapters 1 to 6.

Required output and creative freedom

Build a working interactive dashboard prototype using Google AI Studio or any tool or combination of AIs. Sky is the limit for visual style and features. Include three KPIs, diagnostic evidence, one forecast and a pilot decision area. Minimum interactivity: one control to explore the supplied data and one to change pilot choices, updating costs, impacts and budget feasibility.

Submission

Submit a viewable prototype link or a runnable export such as HTML, an interactive spreadsheet or ZIP, with a brief opening instruction and one screenshot. Put short supporting notes inside the interface or Canvas. Verify that the instructor can open it. A separate PDF report is not required.

1 Find the clues

State the board question and a measurable objective; link your main KPI to its drivers. Calculate net revenue, operating profit and one more KPI for Weeks 1 and 12; show formulas or inputs. Give two supported insights, including one branch or daypart comparison. Offer one rival explanation and say what evidence would help distinguish it.

2 Choose what to trust

Briefly identify the supplied data types, two measurement cautions, one source conflict you reconciled, and one useful missing dataset. Explain the consequence for your analysis. Short dashboard notes or tooltips are enough.

3 Look one week ahead

Choose one simple method to forecast Week 13 completed orders, showing the calculation and assumption. Check the same method by predicting Week 12 using only Weeks 1 to 11; compare with actual Week 12 orders using absolute error = absolute value of actual minus forecast. Explain one operational use and why one check cannot establish reliable accuracy.

4 Pick a pilot and handle the update

Before the minute-55 bulletin, note an initial package, cost and reason. After the bulletin, compare your final choice with one feasible alternative. Either can be do nothing; at least one must be active. Show both costs and their planning four-week incremental impacts in the dashboard. For your chosen row also show the zero-uplift failure impact and ongoing weekly operating profit, using page 4. Explain a trade-off and what the bulletin changed or confirmed. Propose one operational and one inclusion measure, with simple success or stop rules.

5 Make AI earn your trust

Show one short actual analytical prompt and one actual follow-up that questions a consequential claim, assumption or recommendation. Add the key AI proposal, one independent numerical check with its result, and what you changed or retained. Put this in a dashboard notes panel or a short Canvas note. Another AI agreeing is not a sufficient check. Reuse calculations from the tasks above; do not invent an AI mistake or submit full chat logs.

Assessment	Points
Framing and KPI logic	5
Data judgment	10
Analysis and diagnosis	20
Forecast and check	10
Pilot decision and update	20
Prompting and verification	15
Dashboard prototype and creative experience	20

Suggested timing: read 0–10; check analysis 10–25; build prototype 25–55; bulletin and refinement 55–75; test and submit 75–90. Board Bulletin 01 is released at minute 55. One submission only. No video, oral defense, external research or extra process report is required.

The case and weekly ledger

BAYANI BITE is a fictional single operator of three campus food hubs. All ticket values and costs belong to this same operating entity and comparable weekly periods. More entries and larger gross sales have attracted attention, yet queues and operating losses are growing. Operations favors faster service; Marketing favors promotions; Finance wants profit; the student council wants affordable service and cash access. These are viewpoints to investigate, not proven explanations.

Exhibit 1 Twelve week operating ledger

All money is PHP thousands, written PHP k. For example Gross 198 means PHP 198,000. Rows cover the whole network, not separate customers. All records and quotations are invented teaching material.

Week	Entries	Orders	Gross	Disc	Refund	Food	Other op	Wait	Stockouts
1	2100	1260	198	11.0	1.0	98	73.0	8	2
2	2180	1320	205	11.5	1.1	102	75.0	8	2
3	2250	1330	209	12.5	1.0	104	77.5	9	3
4	2400	1370	215	13.5	1.2	110	80.0	10	4
5	2520	1390	221	15.5	1.4	114	84.0	11	6
6	2680	1430	228	17.0	1.8	119	88.0	12	6
7	2750	1440	232	18.5	2.0	122	90.0	14	8
8	2900	1450	238	20.5	2.3	126	93.0	15	10
9	3100	1460	246	24.5	2.5	132	96.0	17	13
10	3300	1450	251	28.5	3.1	136	99.0	19	15
11	3450	1440	254	32.5	3.5	140	103.0	22	18
12	3600	1400	259	36.5	4.2	145	108.0	24	20

Definitions and useful formulas

Field or quantity	Meaning
Entries	Infrared counter observations. Re-entry is possible; not unique customers.
Orders	Completed, reconciled transactions; a person can place more than one.
Net revenue	Gross sales minus recognized discounts minus refunds.
Operating profit	Net revenue minus food and packaging cost minus other operating cost. Other operating cost already includes payroll, rent and utilities.
Possible third KPI	For example orders per recorded entry, discount share of gross sales, net revenue per order, or operating margin. Define your denominator and units.
Wait	Operations' estimated weekly mean end-to-end wait in minutes. Sampling is imperfect; not a median.
Stockouts	Logged unavailability incidents; not units, lost orders or lost customers.

Operating profit is not a bank balance or cash-flow forecast. Taxes, financing and working-capital timing are outside this short case. Do not count food, payroll or intervention benefits twice. An orders-to-entries ratio is a transaction proxy, not unique-customer conversion.

Branch clues survey and source notes

Exhibit 2 Week 12 branch breakdown

Money is PHP k. Branch financial and count totals match the Week 12 network ledger. Local wait samples use different windows and cannot be averaged to reconstruct the network mean.

Branch	Entries	Orders	Gross	Disc	Refund	Food	Other op	Wait	Stockouts
North Gate	1200	540	98	15.0	1.2	54	39	18	4
Library Walk	1100	460	86	11.5	1.6	48	35	23	7
South Quad	1300	400	75	10.0	1.4	43	34	32	9

Peak means 11:30–13:30 and 17:30–19:30 combined. These are subtotals of the same branch counts, not extra orders to add to branch totals.

Branch	Peak entries	Peak orders	Nonpeak entries	Nonpeak orders
North Gate	850	360	350	180
Library Walk	780	260	320	200
South Quad	1000	290	300	110

Field notes: North Gate offered vouchers during the noon rush. Library Walk staff saw people leave queues without a POS record. South Quad noted substitution requests without measuring lost sales. The campaign changed midway through the twelve weeks; there was no controlled experiment.

Exhibit 3 Week 12 survey

A convenience sample of 180 volunteers reported wait categories and whether they intend to buy again within two weeks. This is an intention, not observed repurchase. There are no person-level rows or links to POS records.

Reported wait	Intend to return	Do not intend	Total
10 minutes or less	42	18	60
11 to 20 minutes	36	34	70
More than 20 minutes	16	34	50
Total	94	86	180

Source notes to help your judgment

Issue	What is known
Week 10 discounts	Marketing counted 26.0k public vouchers. Finance counted 28.5k all recognized discounts, including staff offers. The scopes differ.
Week 11 orders	Early export: 1470 before voids. Reconciled ledger: 1440 after 30 voided orders.
Wait observations	Network mean is 24 minutes in Week 12; branch samples have different windows and no aligned sample weights.
Customer and access data	No persistent customer IDs, actual return follow-up, cash-access baseline or budget-meal availability history are supplied. New measurements must be proposed, not invented.

Use the simplest comparison that helps answer your question. Additional statistical tests are optional; any method you choose must fit the evidence.

Pilot menu and simple comparison rules

Exhibit 4 Initial options

All amounts are PHP k. Each option buys a four-week network pilot. Weekly uplift means an estimated improvement in operating profit after recurring costs but before the one-time pilot cost. These estimates are manager and vendor hypotheses, not observed treatment effects. They may fail, overlap or turn negative.

Option	Pilot	One-time cost	Weekly uplift	Possible effect and risk
A	Express pickup counter	18	6 to 13	Wait may fall 4–7 min; counter space needed.
B	Inventory reorder redesign	22	4 to 10	Stockouts may fall 4–9 incidents; supplier lead times uncertain.
C	Replace blanket vouchers	8	5 to 12	Recorded entries may fall 3%–8%; protect affordable meals.
D	Reschedule and cross train crew	12	2 to 7	Wait may fall 2–5 min; staff consent and workload matter.
E	Mobile order pilot	16	3 to 8	Wait may fall 2–6 min; keep an assisted cash-order route.

Budget and scope

Initial one-time budget is 35k. A package may be a single option or a combination; options are indivisible and cannot be repeated. Unspent money is allowed. Do nothing has cost and incremental impact zero. Keep cash payment, existing budget-meal access and staff consent; no involuntary overtime. Necessary setup and access arrangements are included in quoted costs. Do not multiply network benefits by branches or forecast orders.

Planning scenario for comparison

For one active option, use its lower weekly uplift estimate. For a combination, use 75% of the sum of the lower estimates as a shared allowance for overlap and implementation loss. Use the bulletin's latest values. Assume that weekly uplift applies in each of the four pilot weeks. A staged rollout or another benefit assumption can be explored as a separately labeled scenario.

Planning four-week incremental impact = 4 × planning weekly uplift − total one-time cost. Compare your final choice with one feasible alternative using this figure and each cost. At least one row must be active; do nothing may be the other row. You do not need to list every package.

Two extra checks for your chosen row only

Zero-uplift failure impact = minus total one-time cost. This assumes no weekly improvement and no cost recovery; negative operating effects could be worse. Ongoing weekly operating profit = Week 12 operating profit + planning weekly uplift, before one-time pilot spending.

Hold Week 12 operating profit constant only for this simplified financial scenario. The Week 13 order forecast is a separate no-pilot illustration. A positive incremental result means better than doing nothing; it does not necessarily mean BAYANI BITE becomes profitable.

Your board update at minute 55

Read Board Bulletin 01 before finalizing. A short annotation can show what changed or why your initial choice still makes sense. Update the affected dashboard values and labels; a full redesign is not required. Let your interface help the board explore the evidence, choices and remaining uncertainty.
